TreeBUGS: Bayesian Hierarchical MPT Modeling

1. The R package `TreeBUGS`
2. Basic modeling
   - Model fitting
   - Convergence
   - Plots
   - Model fit
3. Advanced modeling
   - Within-subject comparisons
   - Between-subject comparisons
   - Covariates
4. Sensitivity/robustness analysis
   - Priors
   - Predictive distributions
   - Simulation

Software for Hierarchical MPT Models

Software for Hierarchical MPTs

- Implementation of MCMC sampling in R/C/Fortran (Klauer 2010)
- General-purpose software: WinBUGS/JAGS/Stan (Matzke et al. 2015)
- Requires re-implementation of summaries, statistics, plots

TreeBUGS: A user-friendly R package (Heck, Arnold, and Arnold 2018)

- Easy-to-use, open source, free
- Fitting and testing MPT models
    - Posterior sampling, summary statistics, and plots
    - Data generation, robustness simulations
    - Change priors, add predictors, etc.
    - Current limitation: Crossed random effects (persons + items)

Functionality of TreeBUGS

- Input: R objects or text/csv files (minimal R knowledge required)
- Priors and other details can be changed in R
- TreeBUGS translates the model to JAGS (Plummer, 2003) to draw posterior samples
- Functions for post-processing, summaries and plots
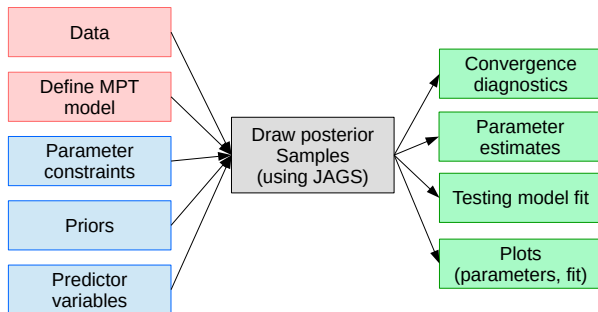

TreeBUGS Paper

CrossMark

TreeBUGS: An R package for hierarchical multinomial-processing-tree modeling

Daniel W. Heck[1] · Nina R. Arnold[1] · Denis Arnold[2,3]

Abstract Multinomial processing tree (MPT) models are a class of measurement models that account for categorical data by assuming a finite number of underlying cognitive process- es. Traditionally, data are aggregated across participants and estimates, fit statistics, and within- and between-subjects com- parisons, as well as goodness-of-fit and summary plots. We also propose and implement novel statistical extensions to include continuous and discrete predictors (as either fixed or

Basic Modeling

(corresponding R script: `07-ApplicationIII-TreeBUGS.R`)

MPT Model Specification

- MPT structure is defined in an EQN model file
  - Simple: copy from multiTree :-)
- Difference: the symbol # allows to add comments

Two-high threshold model
(file: `2htm.eqn`)

```
# Targets
target  hit   do
target  hit   (1-do)*g
target  miss  (1-do)*  (1-g)

# Lures
lure    cr    dn
lure    fa    (1-dn)*g
lure    cr    (1-dn)*(1-g)
```

Data Structure

- Data: Response frequencies in wide format
  - One line per person
  - One category per column
  - Column names must be identical to the EQN categories!
- Either supplied in .csv-file or as `data.frame` / `matrix` in R

Example: `2htm.csv`

```r
# set working directory:
# setwd("D:/R/MPT-workshop/")
frequencies <- read.csv("2htm.csv")
head(frequencies, 5)
```

```
##   cr fa hit miss
## 1 26 24  32   18
## 2 46  4  45    5
## 3 36 14  38   12
## 4 46  4  38   12
## 5 49  1  49    1
```
Heterogeneity

- Load TreeBUGS and plot heterogeneity
- If response frequencies are homogeneous, standard (fixed-effects) MPT models are statistically more efficient

```r
library("TreeBUGS")
plotFreq(frequencies, eqnfile = "2htm.eqn")
```

```r
plotFreq(frequencies, boxplot = FALSE, eqnfile = "2htm.eqn")
```

- Fitting an MPT model in TreeBUGS
    - Model: Text file in EQN syntax (with model equations)
    - Data: `.csv`file
    - Constraints: text file with equality contraints

```r
fit <- traitMPT(eqnfile = "htm.txt",
                data = "responses.csv",
                restrictions = "2htm_constraints.txt")

# beta-MPT: different function, but identical arguments
fit_beta <- betaMPT(eqnfile = "htm.txt",
                    data = "responses.csv",
                    restrictions = "2htm_constraints.txt")
```

Fitting an MPT Model in R

- Alternative: define everything directly in R
  - Model: Text string (`character` in apostrophes)
  - Data: Matrix or data frame
  - Constraints: A list

```
htm <- "
target  hit  do
target  hit  (1-do)*g
target  miss (1-do)*  (1-g)

lure  cr  dn
lure  fa  (1-dn)*g
lure  cr  (1-dn)*(1-g)
"
fit <- traitMPT(eqnfile = htm,
                data = frequencies,
                restrictions = list("dn=do", "g=.50"))
```

Parameter Constraints

Equality constraints

```
# (A) use a general model file and constrain parameters:
fit <- traitMPT(eqnfile = htm,
                data = frequencies,
                restrictions = list("dn=do", "g=.50"))

# (B) hard-coding of constraints in the EQN file:
htm_constr <- "
target  hit   d
target  hit   (1-d)*.50
target  miss  (1-d)*.50

lure    cr    d
lure    fa    (1-d)*.50
lure    cr    (1-d)*.50
"
fit <- traitMPT(eqnfile = htm_constr,
                data = frequencies)
```
Convergence

- Convergence check
  - Posterior/ MCMC samples should look unsystematic (like a hairy caterpillar)
 - For more options, see: `?plot.traitMPT`

```
plot(fit, parameter = "mean", type = "default")
```
Convergence

- Interpreting MCMC plots

Good convergence: 'hairy caterpillar'

Bad convergence: slow movement

Convergence
- Gelman-Rubin statistic ($\hat{R}$)
  - Also known as: "potential scale reduction factor" or "R hat"
  - Similar to ANOVA: Compares between-chain and within-chain variances (large differences between these variances indicate nonconvergence)
  - Statistic should be close to 1 (standard criterion: $\hat{R} < 1.05$)

Good convergence: all chains similar   **Bad convergence: chains differ**
Convergence

- Gelman-Rubin statistic ($\hat{R}$)
  - Columns Rhat and R_95% in the summary output

```
summary(fit)
```

```
## Call:

Daniel W. Heck

Options for MCMC Sampling

- If the model has not converged, it must be fitted with more conservative settings:

```
fit <- traitMPT(
  eqnfile = htm, data = frequencies,
  restrictions = list("dn=do"),

  n.adapt = 5000, # longer adaption of JAGS increases efficiency of sampling
  n.burnin = 5000,# longer burnin avoids issues due to bad starting values
  n.iter = 30000, # drawing more MCMC samples leads to higher precision
  n.thin = 10,    # ommiting every 10th sample reduces memory load
  n.chains = 4)   # more MCMC chains increase precision
```

```
## MCMC sampling started at  2019-04-30 09:36:44
## Calling 4 simulations using the parallel method...
## Following the progress of chain 1 (the program will wait for all
## chains to finish before continuing):
## Welcome to JAGS 4.3.0 on Tue Apr 30 09:36:48 2019
## JAGS is free software and comes with ABSOLUTELY NO WARRANTY
## Loading module: basemod: ok
## Loading module: bugs: ok
## . Loading module: dic: ok
## . Loading module: glm: ok
## . . Reading data file data.txt
## . Compiling data graph
##    Resolving undeclared variables
```

Extend MCMC Sampling

- If the MCMC samples are OK but higher precision is needed:
  - Extend sampling and add new MCMC samples to the fitted JAGS object

```
fit2 <- extendMPT(fit,                # fitted MPT model
                  n.adapt = 2000,     # JAGS need to restart and adapt again
                  n.burnin = 0,       # burnin not needed if previous samples are OK
                  n.iter = 10000)     # how many additional iterations?
```

```
## Calling 4 simulations using the parallel method...
## Following the progress of chain 1 (the program will wait for all
## chains to finish before continuing):
## Welcome to JAGS 4.3.0 on Tue Apr 30 09:37:28 2019

Plot Parameter Estimates

- Estimates for group-level parameters
  - Overall mean μ: Posterior mean and Bayesian credibility interval
  - Individual parameters θ_i: Posterior mean

```
plotParam(fit)
```

roup–level means + 95% CI (red) and individual means
Plot Parameter Estimates

- Plot parameter profiles
  - E.g., assess test-retest reliability of a parameter (Michalkiewicz & Erdfelder, 2016)
- For more options, see: `?plotParam`

```
plotParam(fit, addLines = TRUE, select = c("dn", "g"))
```

roup–level means + 95% CI (red) and individual means
How much did we learn about the parameters?

- Graphical assessment: Plot prior (blue) and posterior (black) densities

```
plotPriorPost(fit)
```

```
## Press <Enter> to show the next plot.
```
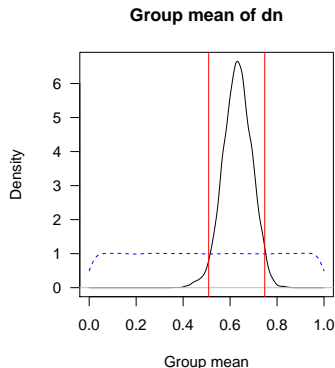

Group-Level Distribution

Distribution of individual estimates

- Histogram: Distribution of θ estimates (posterior mean per person)
- Red density: Estimated group-level distribution

```
plotDistribution(fit)  # graphical test
```

Graphical test of model fit

- Plot means of observed frequencies
- Compare against posterior-predicted frequencies (boxplots)

```
colMeans(frequencies)  # observed group means that are tested
```

```
##    cr    fa   hit  miss
## 39.90 10.10 39.98 10.02
```

```
plotFit(fit)      # graphical test
```

Observed (red) and predicted (boxplot) mean frequencies

- Model fit for *covariance* of observed frequencies

```
cov(frequencies)              # observed covariance matrix that is tested
```

```
##              cr        fa       hit      miss
## cr     84.29592 -84.29592  26.63061 -26.63061

## miss  -26.63061  26.63061 -83.32612  83.32612
```

```
plotFit(fit, stat = "cov")  # graphical test
```

Observed (red) and predicted (gray) covariances
Model Fit: Predicted vs. Observed Data

Testing model fit

- The statistics T1 and T2 quantify the discrepancy between observed and expected means/covariances (similar to Pearson's X^2)
- Posterior predictive p-values
    - Values around .50 indicate good model fit
    - Values close to 0 (or close to 1) indicate misfit
    - In contrast to frequentist p-values, PPP values are *not* uniformly distributed when generating data from the correct model

```
PPP(fit, M = 2000, nCPU = 4)
```

```
## ## Mean structure (T1):
## Observed = 0.03225169 ; Predicted = 0.03227619 ; p-value = 0.495
##
## ## Covariance structure (T2):
## Observed = 6.777547 ; Predicted = 6.895092 ; p-value = 0.504
##
## ## Individual fit (T1):
##     1     2     3     4     5     6     7     8     9    10    11    12
## 0.509 0.524 0.517 0.518 0.567 0.543 0.497 0.552 0.461 0.516 0.492 0.537

##    49    50
```

Modeling with TreeBUGS is simple

1. Define model and clean data
2. Draw MCMC samples
3. Check convergence
4. Check model fit
5. Interpret/plot parameters

Note that these are the usual steps in any Bayesian analysis...

Advanced Modeling

Assessing within-subject differences in parameters

1. Data: Additional columns for separate within-subject conditions
2. Model: Write EQN file for within-subject design
3. MCMC sampling (as usual)
4. Comparison: Compute differences of parameters (transformed parameters)

(1) Data structure for within-subject design

```
freq_within <- read.csv("2htm_within.csv")
head(freq_within, 3)
```

```
##   high_cr high_fa high_hit high_miss low_cr low_fa low_hit low_miss
## 1      44       6       36        14     41      9      40       10
## 2      38      12       39        11     45      5      38       12
## 3      43       7       45         5     34     16      30       20
```

Within-Subject Comparisons

(2) Model: Function for writing within-subject EQN files

- TreeBUGS has a function extends a standard MPT model to multiple within-subject conditions
- Essentially, model equations are copied and each parameter gets a new label (e.g., `d_condition1`)

```
# create EQN file for within-subject manipulations
withinSubjectEQN(htm_d,
                 labels = c("high","low"),   # factor labels
                 constant=c("g"))            # constant parameters
```

```
##              Tree   Category       Equation
## 1   high_target   high_hit           d_high
## 2   high_target   high_hit      (1-d_high)*g
## 3   high_target  high_miss  (1-d_high)*(1-g)
## 4     high_lure    high_cr           d_high
## 5     high_lure    high_fa      (1-d_high)*g
## 6     high_lure    high_cr  (1-d_high)*(1-g)
## 7    low_target    low_hit            d_low
## 8    low_target    low_hit       (1-d_low)*g
## 9    low_target   low_miss   (1-d_low)*(1-g)
## 10     low_lure     low_cr            d_low
## 11     low_lure     low_fa       (1-d_low)*g
## 12     low_lure     low_cr   (1-d_low)*(1-g)
```

Within-Subject Comparisons

(4) Transformed parameters

- Often the interest is in the difference of a parameter across conditions
  - Example: Difference in memory strength $\Delta_d = d_{\text{high}} - d_{\text{low}}$
- Based on the MCMC samples, we can simply compute any function of interest
  - We get a new set of posterior samples that can be summarized as usual

```r
# fit to all conditions:
fit_within <- traitMPT("2htm_within.eqn", "2htm_within.csv")
```

```r
# compute difference in d:
diff_d <- transformedParameters(
  fit_within,
  transformedParameters = list("diff_d = d_high - d_low"),
  level = "group")
summary(diff_d)$statistics
```

```
##          Mean            SD      Naive SE Time-series SE
##   0.3212361182  0.0345022709  0.0003319983   0.0010837807
```

Between-Subject Comparisons

Comparisons in between-subject designs

1) Fit MPT model to each condition separately
   - Separate group-level parameters μ and Σ per group
2) Compute differences in group-level parameters across conditions/models

```
fit1 <- traitMPT(htm_d, "2htm.csv")
fit2 <- traitMPT(htm_d, "2htm_group2.csv")

diff_between <- betweenSubjectMPT(
                fit1, fit2,                  # fitted MPT models
                par1 = "d",                  # parameter to test
                stat = c("x-y","x>y"))       # transformed parameters)
diff_between
```

```
##                Mean    SD  2.5%   50% 97.5% Time-series SE n.eff  Rhat R_95%
## d.m1-d.m2     0.259 0.088 0.085 0.259 0.431          0.005   313 1.013 1.038
## d.m1>d.m2     0.999 0.029 1.000 1.000 1.000          0.000  4967 1.227 1.264
```

Covariates: Correlations

Correlation of MPT parameters with external covariates

- New argument covData: A data frame or file name with values of the covariate(s)
- TreeBUGS computes the correlation of these covariates with the latent person parameters θ (probit values)

```
fit_cor <- traitMPT(htm_d, data = "2htm.csv",
                    covData = "covariates.csv")   # data with covariate(s)

# uncertainty with respect to the MPT parameter estimates:
round(fit_cor$summary$group$cor[,-6], 2)

##                   Mean   SD  2.5%  50% 97.5% n.eff Rhat R_95%
## cor_d_continuous  0.35 0.04  0.28 0.36  0.43  4425    1     1

```
Covariates: Correlations

- Note that the posterior samples of the (descriptive) correlations only reflect uncertainty with respect to the MPT parameters
- We also need to consider the number of participants (sample size)!
- Solution: Use an analytical solution or the posterior distribution of the correlation (Ly et al., 2018)

```
correlationPosterior(fit_cor)
```

```
##                      2.5%   50%  97.5%
## cor_d_continuous    0.06  0.335   0.57
## cor_g_continuous   -0.29  0.035   0.36
```

Covariates: Regression

Regression of MPT parameters on covariates

- Example: Predict memory performance d as a function of age
- Statistically, this requires an regression extension to the model
- The latent probit values θ_i' are predicted by a design matrix X:

$$\theta_i' = \mu + X_i\beta + \delta_i$$

Implementation in TreeBUGS

- Requires only two new arguments to provide the data (age of persons) and the regression structure (predict parameter D_n by age)

```
fit_regression <- traitMPT(htm_d, data = "2htm.csv",
                           covData = "covariates.csv",
                           predStructure = list("d ; continuous"))
```

```
round(fit_regression$summary$group$slope[,-6], 2)
```

```
##    Mean    SD  2.5%   50% 97.5%  n.eff   Rhat  R_95%
##    0.18  0.07  0.04  0.18  0.31 301.00   1.02   1.06
```

Bayes Factor for Covariate

Compute a Bayes factor

- H0: Slope parameter $\beta = 0$
- H1: Slope parameter $\beta \sim$ Cauchy(0, r) (with scale parameter r)
- Method: Savage-Dickey density ratio (Wagenmakers, 2010)
  - Bayes factor H1 vs. H0: prior devided by posterior density (at $\beta = 0$)
  - Only works for simple regression with 1 predictor (Heck 2019)

```
BayesFactorSlope(fit_regression,
                 parameter = "slope_d_continuous",
                 direction = ">",      # H1: positive slope parameter
                 plot = TRUE)          # plot Savage-Dickey density ratio
```

Bayes factor B_10=6.787 (prior red; posterior blue)

Standardized slope parameter: d ~ continuous
```
##                          BF_0>     BF_>0
## slope_d_continuous 0.1473361 6.787201
```

Between-subject designs: Assumptions about the covariance matrix Σ

- **A** Separate covariance matrix per condition: $\Sigma_1, \Sigma_2, \ldots$
  - See previous slides: betweenSubjectMPT(fit1, fit2)
- **B** Identical covariance matrix Σ across conditions
  - Similar to ANOVA: "pooled variance" (Rouder & Morey; 2012)
  - Manipulation only affects the mean parameters μ

```
# fit all between-conditions jointly:
fit_between <- traitMPT(
                htm_d, "2htm.csv",
                covData = "covariates.csv",
                predStructure = list("d ; discrete"),  # discrete predictor
                predType = c("c","f")) # "c" =continuous; "f"=fixed-effects

# get estimates for the group-specific MPT parameters
gmeans <- getGroupMeans(fit_between)
round(gmeans, 2)
```

```
##                     Mean   SD 2.5%  50% 97.5% p(one-sided vs. overall)
## d_discrete[group_a] 0.63 0.09 0.46 0.63  0.79                     0.47
## d_discrete[group_b] 0.65 0.08 0.48 0.65  0.80                     0.47
```

Sensitivity/robustness analysis

Changing Priors

Define different priors

- Prior distributions in the latent-trait MPT necessary for:
    - Latent (probit-) mean μ
    - Latent (probit-) covariance matrix Σ: scaled inverse Wishart with
        - Prior matrix V
        - Degrees of freedom df
        - Scaling parameter ξ
- Example: We assume that guessing probabilities are around 50%

```
fit <- traitMPT(eqnfile="htm.txt", data="responses.csv",
                restrictions=list("dn=do"),

                mu = c(dn = "dnorm(0,1)",    # default prior
                        g = "dnorm(0,5)"),   # prior focused around 50% guessing
                xi = "dunif(0,2)",           # less disperson of MPT parameters
                V = diag(2),                 # default
                df = 2 + 1)                  # default
```
Understanding Priors

**What do the priors actually mean?**

- Draw samples from the prior
- Plot mean/SD of MPT parameters

```
plotPrior(prior =
          list(mu = c(dn = "dnorm(0,1)",    # default prior
                      g  = "dnorm(0,5)"),   # prior focused around 50%
               xi="dunif(0,2)",            # smaller scale for group SD
               V= diag(2), df = 3))        # default Wishart prior
```
Prior on group mean: mu=dnorm(0,1)

Density

Group mean (probability scale)

Prior on group mean: mu=dnorm(0,5)

Density

Group mean (probability scale)

Prior on group SD: xi=dunif(0,2)

Density

Group SD (probit scale)

Prior on group SD: xi=dunif(0,2)

Density

Group SD (probit scale)

# Prior Predictive Sampling

Prior predictive distribution

1. Draw samples from the prior
2. Draw new data (response frequencies)
3. Assess predicted data (e.g., plots or descriptive statistics)

```r
pp <- priorPredictive(prior = list(mu = "dnorm(0,1)", xi="dunif(0,10)",
                                    V=diag(2), df=2+1),
                      eqnfile = htm, restrictions = list("dn=do"),
                      numItems = c(target = 50, lure = 50),
                      N = 50,  M = 500)     # number of participants/samples

# compute and plot predicted values for the average hit/FA rates (in ROC space)
mean_freq <- sapply(pp, colMeans)
par(mar=c(4,5,.1, .1))
plot(mean_freq["fa",]/50, mean_freq["hit",]/50, asp = 1, xlim =0:1, ylim=0:1)
polygon(c(0,1,1), c(0,0,1), col = "gray")
abline(0, 1)
```

Prior Predictive Sampling
Excursion: Different default priors for the scale parameter ξ

1. TreeBUGS (Heck et al., 2018): $\xi \sim \text{Uniform}(0, 10)$
2. Klauer (2010) and Matzke et al. (2015): $\xi \sim \text{Uniform}(0, 100)$

Posterior Predictive

Posterior Predictive Distribution

- What data does the fitted model predict?
- Use posterior samples of the *parameters* to draw new samples of the *data* (i.e., predicted response frequencies)
  - Note: These are the basis of posterior-predictive checks (T1 and T2 statistics)

```
postpred <- posteriorPredictive(fit, M = 100, nCPU = 4)
```

Posterior predicted (mean frequenci

Simulations
Sensitivity and robustness analysis

- Assessing the impact of priors, estimate necessary sample size for specific analysis etc.
    1. Generate data from (correct or wrong) model
    2. Fit model
    3. If necessary: Replicate with a `for`-loop

```r
# standard, fixed-effects MPT (generate data for one person)
sim <- genMPT(theta = c(d = .7, g = .5),
              numItems = c(target = 50, lure = 50),
              eqnfile = htm_d)

# hierarchical MPT (generate a complete table of frequencies)
sim2 <- genTraitMPT(N = 100, eqnfile = htm_d,
                    mean = c(d = .7, g = .5),
                    sigma = c(d = .4, g = .2),
                    rho = diag(2))
```

Appendix

Appendix: Testing for Heterogeneity

- Test by Smith and Batchelder (2008)
  - **A** Test person heterogeneity assuming items homogeneity (χ^2)
  - **B** Test person heterogeneity under item heterogeneity (permutation bootstrap)

```r
# A) chi~2 test
test <- testHetChi(freq = frequencies,
                   tree = c(cr="lure", fa="lure",
                            hit="target",miss="target"))
data.frame(test)
```

```
##     chisq df      prob
## 1 1022.09 98 1.02515e-153
# B) requires data in long format (variables: person / item / response)
# testHetPerm(data, tree, source = "person")
```
Appendix: Convergence

Autocorrelation function

- How strongly are the MCMC samples correlated between iteration t and iteration $t + \text{Lag}$?
- Ideally, these curves should rapidly decrease towards zero.

```
plot(fit, parameter = "mean", type = "acf")
```

Appendix: Convergence

- Plot evolution of Gelman-Rubin statistic
  - Also known as: "potential scale reduction factor" or "R hat"
  - Similar to ANOVA: Compares between-chain and within-chain variances (large differences between these variances indicate nonconvergence)
  - Statistic should be close to 1

```
plot(fit, parameter = "mean", type = "gelman")
```

mean[dn]   mean[g]
MCMC samplers available in TreeBUGS

- Fixed-effects ("standard") MPT: Gibbs sampler in `C++`
- Beta-MPT: `JAGS` and `C++`
- Latent-trait with extensions: `JAGS`
    - Combination of random- and fixed-effects parameters
    - Continuous and categorical covariates
    - Group-level structure: Independent normal distributions
